How to interpret status

Observed: visible in the referenced explorer. Project-reported: supplied by the project. Proposed: a design or operational objective, not a completed milestone.

SECTION 01

Executive summary

A digital unit for shared contribution.

USD Arbitrum (USDA) is an independent token project built around a focused proposition: make contribution-based rewards easier to identify, distribute and understand. The intended application is a team incentive program in which approved contributions are recognized through token allocations and rewards are fulfilled under separately documented program terms.

The project separates the record of a token balance from the commitments of a rewards program. The blockchain records transfers. A program operator defines eligibility, evaluates contributions, manages budgets and delivers any promised benefits. Neither function should be confused with a promise of investment performance.

A token contract is deployed on Arbitrum One and its explorer profile reports verified source code. This paper distinguishes that technical foundation from the operational model and development objectives described below. A deployed contract does not establish that every proposed workflow, integration or market arrangement is already operational. [1]

> **Identity, not a dollar claim**
>
> USDA is presented as a rewards token, not a stablecoin. “USD” forms part of the project name. No dollar reserve, guaranteed USD price or unconditional redemption at $1 is represented by this document.

Three design priorities

Priority	Practical meaning
Recognizable participation	A common unit for approved contributions and clearly defined program benefits.
Verifiable information	A contract identifier, published token parameters and a documented distinction between facts and plans.
Operational discipline	Defined responsibilities, controlled treasury workflows and reviewable changes.

The ambition is long-term usefulness through consistent execution, not complexity for its own sake. This edition documents the project’s scope, token profile, proposed operating model, material dependencies and risk boundaries. It does not promise perpetual operation, market access or financial returns.

SECTION 02

Token identity & profile

One network. One contract identifier.

The authoritative identifier for this edition is the combination of Arbitrum One and the contract address below. A name, ticker, logo or search result alone is not a sufficient identifier. Other projects may use similar names or the same ticker.

Parameter	Value / evidence
Project / ticker	USD Arbitrum / USDA
Network / chain ID	Arbitrum One / 42161 [3]
Token standard	ERC-20 [1] [2]
Contract address	`0x76176ED3F1682FC55419EBD335ABf56838aE646f`
Decimals	6; the smallest displayed unit is 0.000001 USDA [1]
Total token supply	4,060,968,375 USDA, as displayed by Arbiscan [1]
Raw-unit equivalent	4,060,968,375,000,000 base units; calculated using 6 decimals
Source verification	Exact Match, as displayed by Arbiscan [1]
Contract name	USDArbitrum [1]

Circulating supply is a separate disclosure

The project has reported circulating supply of 4,060,968,375 USDA. This is a project-reported figure, not an independently verified public-float calculation or an approval by a data provider. Section 05 explains the distinction.

Document baseline

Version 1.0 is prepared on 20 October 2026. Explorer observations are a publication-time reference, not a block-pinned attestation. Reader verification should use the current contract and relevant on-chain records. This paper is not a security audit or a complete reconstruction of deployment history.

Only the Arbitrum One contract identified here is covered. No additional chain deployment, canonical bridge, reserve vehicle or separate investment product is represented in this edition.

SECTION 03

Purpose & design principles

Contribution first. Complexity only where it adds value.

The problem being addressed

A team rewards program needs more than a points balance. Participants need to understand what earns recognition, how an award is approved and how a benefit is delivered. Operators need a consistent record, a defined budget and a process for resolving errors. USDA's proposed role is a common digital unit within that workflow.

Tokenization is useful only where it improves that experience. It does not replace sound program administration, contractual obligations or a clear description of benefits. The project therefore keeps recognition, token transfers and reward fulfillment as distinct activities with distinct responsibilities.

Design principles

Principle	Application to USDA
Purpose before features	Prioritize contribution-based rewards over speculative feature expansion.
Clear boundaries	Distinguish program benefits, token ownership and any external market price.
Evidence before claims	Identify completed work separately from proposals, estimates and third-party decisions.
Interoperability	Use a standard token interface rather than a proprietary balance format.
Privacy by restraint	Keep names, task details and employment information outside public transaction records.

Scope and non-goals

The proposed scope includes approved team awards, participant balances and reward requests under a program's own terms. This edition does not describe a lending protocol, deposit product, copytrading service, yield strategy, governance DAO or collateralized currency.

The intended audience is a participating team and its program operators. That intended use is not an on-chain access boundary. Transferable tokens may reach addresses outside the original group; internal participation rules do not make a public blockchain private.

SECTION 04

System architecture

Separate the ledger, the workflow and the interface.

Token layer

ERC-20 defines a shared interface for balances, transfers and spending allowances. The published USDA ABI includes the standard balance and supply queries, transfer methods and approvals. An allowance authorizes a spender; it is not a reward entitlement. [1] [2]

Program layer

The proposed operating layer records task approval, participant eligibility, allocation decisions and fulfillment status. These records are maintained outside the token contract. A blockchain transfer can evidence delivery of tokens, but it does not establish that a task was completed or that a physical prize was supplied.

Wallet and presentation layer

Safe is the intended treasury and participant-wallet environment. A wallet can present assets, but discovery, logos and fiat valuations remain separate integrations. Successful token deployment is not proof that every interface will display the token or its price. [4] [5]

> **Published interface: scope of the observation**
>
> The published ABI does not expose mint, burn, pause, blacklist, owner or upgrade functions. This is an interface-level observation, not a comprehensive finding about implementation security or immutability. No independent audit is claimed in this edition. [1]

The accounting unit is USDA; network execution costs are separate. Applications must use integer base units and the declared decimals when constructing transactions. Interface formatting must not change balances or imply a fixed exchange rate. [2]

SECTION 05

Supply & allocation disclosure

Issued quantity is not the same as public float.

The token profile records a total supply of 4,060,968,375 USDA. At six decimal places this corresponds to 4,060,968,375,000,000 base units. Token quantity is not a statement of dollar reserves, treasury purchasing power, project valuation or funds available for redemption. [1]

Circulating-supply treatment

Project materials report the same quantity as circulating supply. This paper retains that figure only as a project-reported disclosure. Minting tokens, keeping them unlocked or moving them among controlled addresses does not by itself establish public circulation. Data providers may exclude treasury, insider, restricted or earmarked holdings under their own methodologies. [6]

A reproducible public-float disclosure requires a dated wallet inventory, ownership or control classifications, relevant restrictions and a documented calculation. This edition does not independently certify that all issued tokens are held by unrelated public participants.

Disclosure item	Position in this edition
Total supply	Explorer-reported token quantity; see token profile.
Circulating supply	Project reports 4,060,968,375 USDA; independently verified float is not established.
Allocation percentages	No approved allocation schedule is specified in this edition.
Treasury and team wallets	A complete address inventory and control map are not included.
Vesting / lockups	No schedule or enforceable lock is asserted.
Liquidity commitments	No guaranteed amount, duration or lock is asserted.

Disclosure framework

A future allocation register should separate reward inventory, operating holdings, liquidity positions and any other earmarked balances. Each line should identify its purpose, wallet or contract, responsible controller, restrictions and the date of measurement. Categories are a reporting framework, not an allocation already approved.

> **No automatic valuation**
>
> Multiplying total supply by a hypothetical $1 price would not establish a realizable market capitalization, backing level or redemption capacity.

SECTION 06

The rewards operating model

A proposed process, from contribution to fulfillment.

The following workflow describes the intended program model. It is not an assertion that an automated rewards platform is already live. Participation conditions and benefit commitments must be documented by the operator before the relevant program begins.

Stage	Responsibility and record
01 · Define	Publish eligible contributions, award criteria, limits, review process and participant terms.
02 · Approve	Record the accepted contribution and award amount in the program's internal system.
03 · Distribute	Transfer the approved token amount from a designated wallet and reconcile the transaction hash.
04 · Request	Allow an eligible participant to request a benefit under the applicable program rules.
05 · Fulfill	Complete the agreed token-return process and deliver the benefit; retain an auditable fulfillment record.

Program benefits and market prices

An operator may define prizes or cash-denominated benefits for eligible participants, subject to separate terms and applicable requirements. Such a commitment must identify who owes what, to whom, under which conditions and within what limits. It is not a universal right for every token holder to redeem USDA at a fixed dollar price.

Returned tokens and reconciliation

A returned token balance is not a burn. In the proposed base workflow, returned tokens go to a designated program wallet and any reuse is governed by program rules. No automatic supply reduction should be claimed without a supported contract mechanism and evidence.

For illustration only: an approved contribution may earn 100 USDA, later applied toward an eligible benefit. The example sets no price, conversion rate, catalog entitlement or funding commitment. Those details belong in the actual program terms.

> **Operating controls**
>
> The proposed design uses unique award identifiers, independent approval where practical and a reconciliation record linking the award, transfer and fulfillment. Personal details stay in controlled off-chain records.

SECTION 07

Treasury, custody & governance

Control is an operational responsibility.

Decision-making model

USDA is described as a project-led initiative, not as a token-governed DAO. Holding tokens does not, by itself, confer equity, a claim on company profits, treasury ownership or a vote over program administration. Any separate agreement would need to define its own rights and obligations.

Contract-level functionality and control of existing token balances are different issues. Even a simple token interface does not prevent a treasury controller from moving inventory or an operator from changing future program budgets. Participants should evaluate those dependencies separately.

Proposed custody framework

Safe is the intended environment for collective treasury control. Before claiming a multisignature treasury is operational, the project should identify the actual wallet, signing threshold, relevant permissions and recovery procedure. This edition does not assert a deployed treasury configuration.

Responsibility	Proposed control
Award authorization	Separate the approval of contributions from transaction preparation where practical.
Treasury execution	Use designated wallets, defined approval limits and a reviewable transaction record.
Operating automation	Limit bot-wallet balances and approvals; keep the principal treasury outside routine automation.
Incident response	Maintain escalation contacts and a process to suspend off-chain operations where needed.
Reconciliation	Compare program liabilities, fulfilled benefits, token inventory and external assets separately.

Change management

Material changes should be versioned and announced before taking effect, with separate treatment for existing commitments and future participation. Updating a whitepaper does not amend deployed bytecode or retroactively erase obligations. A new contract, migration or additional chain would require its own identifiers and disclosures.

> **Continuity is a goal, not a guarantee**
>
> A long-term operating horizon depends on resources, responsible execution and ongoing decisions. Token ownership does not guarantee perpetual support or availability of future rewards.

SECTION 08

Market structure & asset visibility

Token ownership, price discovery and program value are distinct.

External trading

Where a trading venue and liquidity exist, unrelated parties may transact in USDA. A Uniswap swap link is a route to an interface, not proof of a funded pool, deep liquidity or a successful trade. The project does not guarantee that a particular order can be executed.

Automated-market-maker prices depend on trading conditions and pool design. Liquidity is a trading resource, not necessarily collateral available to holders. In Uniswap v2, for example, reserve ratios and liquidity-provider positions determine pool mechanics; that example does not identify which version or pool USDA uses. [7]

No guaranteed dollar price

USDA is not represented as redeemable on demand for one US dollar. No collateral redemption system, price floor, mandatory buyback or uninterrupted peg defense is specified in this edition. The token's name is not an executable price promise.

Any future treasury intervention or external market-making arrangement would require separate disclosure of its objectives, controller, inventory, limitations, conflicts and shutdown conditions. A reference-price objective, including $1, would not on its own create a redemption right or eliminate the possibility of losses. No active strategy is confirmed here.

Discovery and data providers

Safe documents default token discovery through Zerion with spam filtering. Zerion classifies assets using multiple signals. Correct transfer functionality therefore does not guarantee default visibility, an image or a fiat quote. [4] [5]

CoinGecko and CoinMarketCap are independent services. A homepage link, application or project description is not an approved listing. This edition makes no claim of their endorsement, verified circulating supply or guaranteed inclusion.

> **Publication discipline**
>
> Market announcements should identify the actual pool or asset-page URL and the date checked. Displayed valuations should never be presented as a guaranteed exit value or as funds reserved for reward fulfillment.

SECTION 09

Security & material risks

Verification improves observability. It does not remove risk.

Arbiscan displays Exact Match source verification for the contract. This is not an independent security audit, an economic assessment or a guarantee of safety. This edition claims none of those. [1]

Risk	Why it matters / proposed response
Contract and integration	Implementation defects or incompatible integrations may lead to loss. Test actual workflows; commission review proportionate to exposure.
Custody and approvals	Compromised keys, signers or allowances can cause unauthorized transfers. Use scoped permissions and transaction review.
Market and liquidity	Price may fall sharply, routes may disappear and liquidity may be withdrawn. Do not equate a screen price with realizable proceeds.
Concentration	A small number of controllers may hold material inventory. Publish wallet classifications before making distribution claims.
Program fulfillment	An operator may lack resources or fail to deliver benefits. Define and fund commitments separately from token valuations.
Network and service access	Chain, RPC, wallet, explorer or data-provider interruptions may delay access. Maintain fallback verification and support procedures.
Privacy and social engineering	Public transfers can reveal relationships; copied names and logos can mislead. Minimize personal on-chain data and verify full identifiers.
Legal and tax	Token distribution and benefits may trigger obligations. Obtain jurisdiction-specific review before offering a program or market service.

Risk controls above are design recommendations, not an assertion that every control has been deployed. Participants should not rely on branding, an explorer badge or a roadmap as a substitute for understanding the actual implementation and obligations.

Loss and recovery

USDA may lose some or all market value. On-chain mistakes may be irreversible, and recovery of lost keys or mistaken transfers is not guaranteed. No principal protection, deposit insurance or minimum return is represented.

SECTION 10

Development roadmap

Progress is measured by evidence, not by deadlines alone.

The roadmap is a sequence of intended work, not a guarantee of delivery. It avoids unsupported dates and separates observed contract facts from work requiring operational completion or third-party review.

Stage	Scope / completion evidence	Position
01 · Foundation	Contract identifier and published token profile; explorer source-verification status.	Observed [1]
02 · Program readiness	Participation terms, benefit budget, wallet inventory, approval roles and reconciliation procedure.	Proposed / not certified
03 · Controlled pilot	Real participant workflow from approved award to completed benefit; documented issues and fixes.	Planned objective
04 · Public data quality	Consistent metadata, logo, contract references and provider-specific review where needed.	Third-party dependent
05 · Ongoing operation	Versioned updates, treasury reporting, support process and assessment of further use cases.	Long-term objective

Suggested operational indicators

Useful measures include reconciled awards, successful benefit fulfillment, unresolved support cases, completion time and budget coverage. These are proposed indicators, not published performance statistics. No target number of holders, partners or daily transactions is asserted.

Review gates

A stage should advance when its evidence is available, not merely because a campaign date has arrived. Funding, technical testing, legal review and third-party dependencies may change the order or scope of work. A material change should result in an updated document or a dated project notice.

> **Communications standard**
>
> Describe shipped functionality as shipped, planned work as planned and external decisions as external. A roadmap should not be used as proof of an audit, listing, price support or partnership.

SECTION 11

Disclosures & publication policy

Independent project. Explicit boundaries.

Brand and affiliation

USD Arbitrum (USDA) is an independent token project. It is not USDT, USDC or USDS, and is not represented as a digital claim on US dollars. No affiliation, sponsorship or endorsement by Tether, Circle, Sky, the Arbitrum Foundation or Offchain Labs is claimed. The same applies to Safe, Zerion, Uniswap, CoinGecko and CoinMarketCap.

References to networks, interfaces and standards describe intended use or technical context. They do not turn USDA into an official asset of those organizations. Projects sharing the USDA ticker remain separate assets unless an explicit, verifiable relationship is published.

Nature of this document

This is a project and technical overview, not an investment recommendation, a warranty, a reserve attestation, an audit report or a promise to deliver tokens, returns or benefits. It is not represented as a regulator-approved disclosure or as satisfying any jurisdiction's statutory whitepaper requirements.

The label "rewards token" describes intended use; it is not a legal determination. Any actual issuance, public offering, financial activity or employee program requires review of applicable obligations. A disclaimer cannot override the project's real features, conduct or separately enforceable commitments.

Evidence and version control

This edition distinguishes three types of information: explorer-observed technical facts; statements supplied by the project; and proposed operating practices. Project-reported circulation, contact information and leadership attribution are not independently attested here. Operational recommendations are not advertised as already implemented.

The Markdown and PDF editions should carry the same release version. Substantive updates should be recorded in the changelog and retained in repository history. Corrections to material facts should identify what changed and why.

> **Source of rights and obligations**
>
> Participation terms must separately specify the operator, eligibility, benefits, limits, funding and dispute process. A token balance alone does not define those commitments. This document does not eliminate any rights arising under applicable law or a valid separate agreement.

SECTION 12

Reader’s verification guide

Check the asset, the evidence and the operating terms.

Before relying on project information

Check	What to establish
Identity	The complete contract address and Arbitrum One chain ID match this document.
Contract facts	Review the current explorer profile, implementation and callable functions; do not treat an ABI review as an audit.
Supply	Separate issued quantity from independently supported circulation; examine controlled wallets and restrictions.
Program terms	Identify the operator, participant eligibility, benefit rules and any funding or fulfillment limits.
Market claims	Verify actual venues and liquidity rather than inferring them from a swap link or displayed price.
Document version	Use a dated release and review material corrections before relying on an older copy.

Working definitions

Term	Meaning in this paper
Total supply	The issued token quantity; not a valuation or a fiat reserve.
Circulating supply	A methodology-dependent measure of public circulation, distinct from total or unlocked supply. [6]
Treasury inventory	Token balances or other assets controlled for project or program operations.
Reward fulfillment	Delivery of a separately defined participant benefit, not merely a token transfer.
Liquidity	Assets and market conditions supporting exchange; not a guaranteed exit at a quoted price.
Source verification	An explorer’s code-matching status; not an assertion of independent audit.

When information is missing or inconsistent, request clarification through the project’s published contact channel before relying on it. The relevant project identifiers and source references follow.
